Geometric interpretation

Lines in 2D space - row solution Equations are considered isolation

$$2x - y = 1$$

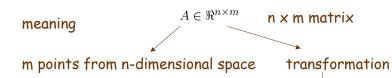

$$x+y = 5$$

Linear combination of vectors in 2D Column solution

$$\left[\begin{array}{c}2\\1\end{array}\right]x+\left[\begin{array}{c}-1\\1\end{array}\right]y=\left[\begin{array}{c}1\\5\end{array}\right]$$

We already know how to multiply the vector by scalar

Matrices

$$C = AA^T$$

Covariance matrix - symmetric Square matrix associated with The data points (after mean has been subtracted) in 2D

$$C = \begin{bmatrix} \sum_{1}^{n} x_i^2 & \sum_{1}^{n} x_i y_i \\ \sum_{1}^{n} x_i y_i & \sum_{1}^{n} y_i^2 \end{bmatrix}$$

$$A \in \Re^{2 \times 2}$$

$$y = Ax$$

Special case matrix is square

Linear equations

In 3D

$$\begin{bmatrix} 2 & 1 & 1 \\ 4 & -6 & 0 \\ -2 & 7 & 2 \end{bmatrix} \begin{bmatrix} u \\ v \\ w \end{bmatrix} = \begin{bmatrix} 5 \\ -2 \\ 9 \end{bmatrix}$$

When is RHS a linear combination of LHS

$$\begin{bmatrix} 2\\4\\-2 \end{bmatrix} u + \begin{bmatrix} 1\\-6\\7 \end{bmatrix} v + \begin{bmatrix} 1\\0\\2 \end{bmatrix} w = \begin{bmatrix} 5\\-2\\9 \end{bmatrix}$$

$$A\mathbf{x} = \mathbf{y}$$
$$det(A) \neq 0$$
$$A^{-1}A\mathbf{x} = A^{-1}\mathbf{y}$$
$$\mathbf{x} = A^{-1}\mathbf{v}$$

Linear equations

Not all matrices are invertible

- inverse of a 2x2 matrix (determinant non-zero)inverse of a diagonal matrix
- Computing inverse solve for the columns
 Independently or using Gauss-Jordan method

$$\begin{bmatrix} 2 & 1 & 1 \\ 4 & -6 & 0 \\ -2 & 7 & 2 \end{bmatrix} \begin{bmatrix} \mathbf{x}_1 & \mathbf{x}_2 & \mathbf{x}_3 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Vector subspace

A subspace of a vector space is a non-empty set Of vectors closed under vector addition and scalar multiplication

Example: overconstrained system - more equations then unknowns

$$\begin{bmatrix} u_1 & v_1 \\ u_2 & v_2 \\ u_3 & v_3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$$

The solution exists if $\,b$ is in the subspace spanned by vectors $\,u$ and $\,v$

$$\begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} x_1 + \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} x_2 = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}$$

Vector spaces (informally)

- · Vector space in n-dimensional space \Re^n
- n-dimensional columns with real entries
- Operations of addition, multiplication and scalar multiplication
- Additions of the vectors and multiplication of a vector by a scalar always produces vectors which lie in the space
- Matrices also make up vector space e.g. consider all 3x3 matrices as elements of \Re^9 space

Linear Systems - Nullspace

- 1. When matrix is square and invertible
- 2. When the matrix is square and noninvertible
- 3. When the matrix is non-square with more constraints then unknowns

$$A\mathbf{x} = \mathbf{b}$$

Solution exists when b is in column space of A Special case

All the vectors which satisfy $A\mathbf{x}=0$ lie in the NULLSPACE of matrix A

Basis

n x n matrix A is invertible if it is of a full rank

Rank of the matrix - number of linearly independent rows (see definition next page)

If the rows of columns of the matrix A are linearly independent - the nullspace of contains only 0 vector

Set of linearly independent vectors forms a basis of the vector space

Given a basis, the representation of every vector is unique Basis is not unique (examples)

Change of basis

Fact A.6 (Properties of basis). Suppose B and B' are two bases for a linear space V. Then

2. Let $B = \{b_i\}_{i=1}^n$ and $B' = \{b_i'\}_{i=1}^n$, then each base vector of B can be expressed as linear combination of those in B', i.e.

$$b_j = a_{1j}b'_1 + a_{2j}b'_2 + \dots + a_{nj}b'_n = \sum_{i=1}^n a_{ij}b'_i.$$
 (A.2)

for some $a_{ij} \in \mathbb{R}, i, j = 1, 2, \dots, n$.

3. For any vector $v \in V$, it can be written as a linear combination of vectors in either of the bases

$$v = x_1b_1 + x_2b_2 + \dots + x_nb_n = x_1'b_1' + x_2'b_2' + \dots + x_n'b_n'$$
 (A.3)

where the coefficients $\{x_i \in \mathbb{R}\}_{i=1}^n$ and $\{x_i' \in \mathbb{R}\}_{i=1}^n$ are uniquely determined and are called the coordinates of v with respect to each basis.

Linear independence

Definition A.1 (A linear space). A set (of vectors) V is considered as a linear space over the field \mathbb{R} , if its elements, so-called vectors, are closed under two basic operations: scalar multiplication and vector summation. That is, given any two vectors $v_1, v_2 \in V$ and any two scalars $\alpha, \beta \in \mathbb{R}$, the linear combination $v = \alpha v_1 + \beta v_2$ is also a vector in V.

Definition A.4 (Linearly independence). A set of vectors $S = \{v_i\}_{i=1}^m$ is said to be linearly independent if the equation

$$\alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_m v_m = 0$$

implies

$$\alpha_1 = \alpha_2 = \dots = \alpha_n = 0.$$

Definition A.5 (Basis). A set of vectors $B = \{b_i\}_{i=1}^n$ of a linear space V is said to be a basis if B is a linearly independent set and B spans the entire space V (i.e. V = span(B)).

Change of basis (contd.)

$$[b_1, b_2, \dots, b_n] = [b'_1, b'_2, \dots, b'_n] \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}.$$

$$v = [b_1, b_2, \dots, b_n] \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = [b'_1, b'_2, \dots, b'_n] \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}$$

$$B' = BA^{-1}, \quad x' = Ax.$$

Linear Equations

Vector space spanned by columns of A $\begin{bmatrix} 2 \\ 4 \\ -2 \end{bmatrix} u + \begin{bmatrix} 1 \\ -6 \\ 7 \end{bmatrix} v + \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix} w = \begin{bmatrix} 5 \\ -2 \\ 9 \end{bmatrix}$

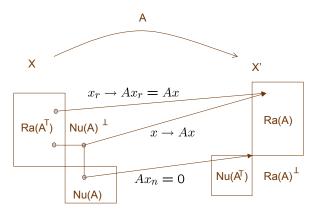

In general

$$A\in\Re^{n\times m}$$

Four basic subspaces

- Column space of A dimension of C(A)number of linearly independent columns r = rank(A)
- Row space of A dimension of R(A) number of linearly independent rows $r = rank(A^T)$
- Null space of A dimension of N(A) n r
- Left null space of A dimension of $N(A^T)$ m r
- · Maximal rank min(n,m) smaller of the two dimensions

Structure induced by a linear map

Linear Equations

Vector space spanned by columns of A $\begin{bmatrix} 2\\4\\-2 \end{bmatrix} u + \begin{bmatrix} 1\\-6\\7 \end{bmatrix} v + \begin{bmatrix} 1\\0\\2 \end{bmatrix} w = \begin{bmatrix} 5\\-2\\9 \end{bmatrix}$

In general

$$A \in \Re^{n \times m}$$

Four basic possibilities, suppose that the matrix \boldsymbol{A} has full rank Then:

- \bullet if n < m number of equations is less then number of unknowns, the set of solutions is (m-n) dimensional vector subspace of R^m
- if n = m there is a unique solution
- \bullet if n \rightarrow m number of equations is more then number of unknowns, there is no solution

Linear Equations - Square Matrices

- 1. A is square and invertible
- 2. A is square and non-invertible
- 1. System Ax = b has at most one solution $x = A^{-1}y$ columns
 - are linearly independent rank = n
 - then the matrix is invertible
- 2. Columns are linearly dependent rank < n
 - then the matrix is not invertible

Linear Equations - non-square matrices

Long-tin matrix over-constrained system

$$\begin{bmatrix} 2\\3\\4 \end{bmatrix} \mathbf{x} = \begin{bmatrix} b_1\\b_2\\b_3 \end{bmatrix} \qquad a\mathbf{x} = b$$

The solution exist when b is aligned with [2,3,4]^T

If not we have to seek some approximation - least squares Approximation - minimize squared error

$$e^2 = (2x - b_1)^2 + (3x - b_2)^2 + (4x - b_3)^2$$

Least squares solution - find such value of x that the error Is minimized (take a derivative, set it to zero and solve for x) Short for such solution

$$a\mathbf{x} = b$$

$$e^2 = \|ax - b\|^2$$

$$\bar{\mathbf{x}} = \frac{a^T b}{a^T a \mathbf{x}}$$

$$\bar{\mathbf{x}} = \frac{a^T b}{a^T a}$$

Homogeneous Systems of equations

$$A\mathbf{x} = 0$$

When matrix is square and non-singular, there a Unique trivial solution x = 0

If $m \ge n$ there is a non-trivial solution when rank of A is rank(A) < n

We need to impose some constraint to avoid trivial Solution, for example $\|\mathbf{x}\|=1$

Find such x that
$$\|A\mathbf{x}\|^2$$
 is minimized $\|A\mathbf{x}\|^2 = \mathbf{x}A^TA\mathbf{x}$

Solution: eigenvector associated with the smallest eigenvalue

Linear equations - non-squared matrices

Similarly when A is a matrix

$$\begin{bmatrix} 1 & 2 \\ 1 & 3 \\ 0 & 0 \end{bmatrix} \mathbf{x} = \begin{bmatrix} 4 \\ 5 \\ 6 \end{bmatrix}$$

$$A\mathbf{x} = b$$

$$A^{T}A\mathbf{x} = A^{T}b$$

$$\bar{\mathbf{x}} = (A^{T}A)^{-1}A^{T}b$$

 \cdot If A has linearly independent columns A^TA is square, symmetric and invertible

$$A^{\dagger} = (A^T A)^{-1} A^T$$

is so called pseudoinverse of matix A

Eigenvalues and Eigenvectors

- Motivated by solution to differential equations
- For square matrices $A \in \Re^{n \times n}$ $\dot{\mathbf{u}} = A\mathbf{u}$ $A = \begin{bmatrix} 4 & -5 \\ 2 & -3 \end{bmatrix}$

For scalar ODE's

$$\dot{u} = au$$

$$u(t) = e^{at}u(0)$$

We look for the solutions of the following type exponentials

$$v(t) = e^{\lambda t} y$$

$$w(t) = e^{\lambda t} z$$

Substitute back to the equation

$$\lambda e^{\lambda t} y = 4e^{\lambda t} y - 5e^{\lambda t} z$$

$$\lambda e^{\lambda t} z = 2e^{\lambda t} y - 3e^{\lambda t} z$$

$$\mathbf{x} = \begin{bmatrix} y \\ z \end{bmatrix} \qquad \lambda \mathbf{x} = \begin{bmatrix} 4 & -5 \\ 2 & -3 \end{bmatrix} \mathbf{x}$$

Eigenvalues and Eigenvectors

$$\lambda \mathbf{x} = \begin{bmatrix} 4 & -5 \\ 2 & -3 \end{bmatrix} \mathbf{x} \qquad A\mathbf{x} = \lambda \mathbf{x}$$
 eigenvector eigenvalue

Solve the equation:

$$(A - \lambda I)\mathbf{x} = 0 \tag{1}$$

x - is in the null space of $(A - \lambda I)$

 λ is chosen such that $(A-\lambda I)$ has a null space

Computation of eigenvalues and eigenvectors (for dim 2,3)

- 1. Compute determinant
- 2. Find roots (eigenvalues) of the polynomial such that determinant = 0
- 3. For each eigenvalue solve the equation (1)
 For larger matrices alternative ways of computation

Eigenvalues and Eigenvectors

$$A\mathbf{x} = \lambda \mathbf{x}$$

Only special vectors are eigenvectors

- such vectors whose direction will not be changed by the transformation A (only scale)
- they correspond to normal modes of the system
 act independently
 eigenvalues
 eigenvectors

Examples

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix}$$

2, 3

$$\left[\begin{array}{c} 0 \\ 1 \end{array}\right]; \left[\begin{array}{c} 1 \\ 0 \end{array}\right]$$

Whatever A does to an arbitrary vector is fully determined by its eigenvalues and eigenvectors

$$A\mathbf{x} = 2\lambda_1 v_1 + 5\lambda_2 v_2$$

Eigenvalues and Eigenvectors

For the previous example

$$\lambda_1 = -1, x_1 = [1, 1]^T$$
 $\lambda_2 = -2, x_2 = [5, 2]^T$

We will get special solutions to ODE $\dot{\mathbf{u}} = A\mathbf{u}$

$$A\mathbf{u} = e^{\lambda_1 t} \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$
 $\mathbf{u} = e^{\lambda_2 t} \begin{bmatrix} 5 \\ 2 \end{bmatrix}$

Their linear combination is also a solution (due to the linearity of $\dot{\mathbf{u}} = A\mathbf{u}$)

$$\mathbf{u} = c_1 e^{\lambda_1 t} \begin{bmatrix} 1 \\ 1 \end{bmatrix} + c_2 e^{\lambda_1 t} \begin{bmatrix} 5 \\ 2 \end{bmatrix}$$

In the context of diff. equations – special meaning Any solution can be expressed as linear combination Individual solutions correspond to modes

Eigenvalues and Eigenvectors - Diagonalization

 Given a square matrix A and its eigenvalues and eigenvectors - matrix can be diagonalized

$$A = S \wedge S^{-1}$$
 Matrix of eigenvectors Diagonal matrix of eigenvalues
$$AS = \Lambda S$$

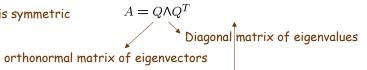

• If some of the eigenvalues are the same, eigenvectors are not independent

Diagonalization

- · If there are no zero eigenvalues matrix is invertible
- · If there are no repeated eigenvalues matrix is diagonalizable
- · If all the eigenvalues are different then eigenvectors are linearly independent

For Symmetric Matrices

If A is symmetric

i.e. for a covariance matrix or some matrix $B = A^TA$

Example - line fitting

Equation of a line

$$ax + by = d$$

Line normal

$$\mathbf{n} = [a, b]$$

Distance to the origin $\,d\,$

Error function
$$e(a,b,d) = \sum_{i=1}^{n} (ax_i + by_i - d)^2$$

Differentiate with respect to a,b,d set the first derivative to 0 and solve for the parameters

Symmetric matrices (contd.)

$$A^TA = V \operatorname{diag}\{\sigma_1^2, \sigma_2^2, \dots, \sigma_n^2\}V^T$$

$$||A||_f = \sqrt{\sum_{i,j} a_{ij}^2}.$$

$$||A||_f \doteq \sqrt{\operatorname{trace}(A^T A)} = \sqrt{\sigma_1^2 + \sigma_2^2 + \dots + \sigma_n^2}.$$
